This technique aims to treat each application as a service that provides a set of features to other applications. For example, a customer care application may be treated as a service that provides customer data to another application. The service-oriented architecture is particularly useful for interapplication communication. For example, a web-based banking application may communicate with another application to transfer money from a checking account to a savings account. In this example, the web-based banking application acts as a service that provides money transfer capabilities to another application. The above example illustrates how service-oriented architecture may be used to enhance the functionality of an application. More generally, service-oriented architecture may be used to improve the performance of existing applications. In order to improve the performance of an existing application, the existing application may be modified to act as a service. For example, a business management application, when treating its own data, may be seen as a service that provides data to other applications. Modifying an existing application to act as a service may involve significant costs. For example, modifying the existing application to act as a service may require modifications to the code and may require time to test the modified application. The time spent on modifying the existing application may be in excess of the time spent creating the application in the first place. There is therefore a need for an improved technique to modify an existing application to act as a service. Serotonergic and GABAergic mechanisms in the control of food intake. The role of serotonin (5-hydroxytryptamine) (5-HT) and gamma-aminobutyric acid (GABA) in the control of food intake is assessed. Dopamine (DA 2d92ce491b
