is a free e-book to download as a PDF (.pdf) file. It must be understood that the "distribution of radii" for the transition from point A to point B is a purely mathematical term that is not commonly used in teaching staff. Any distribution is described as follows: the center of mass is a point on the line AB and the instantaneous center of mass (G) is the point of intersection of line A with line BC. These points are called centers of mass, and they have the same radius, the same length and the same volumes in the coordinate system, that is, they are equal. But on the surface of the Earth, these distances are different - in contrast to the formulas that are used to calculate orbits. Any speed is associated with pressure and weight, and we know that on the surface of the Moon there is only gravity (gained on cables in space), and on Earth there is also gravity and weight. Therefore, it is impossible to calculate the orbit on the Moon according to the formulas that are compiled for the Earth - already in the conditions of "low" gravity on Earth, all these forces can play a role. Therefore, it is necessary to take only those parameters that can be calculated on the Earth with sufficient accuracy (in the case of the lunar "coordinate system" these are the radius and mass of the Earth), and conclude that they correspond to the formulas. "At first" it's not difficult, but when it already works, you need to base them on something - that is, not just draw a conclusion about the correspondence of the formulas - for example, according to their "satellite effects", but take it for granted that all these parameters always and everywhere follow from the formula, and do not at all require additional conditions of "compatibility" with the Earth. And when this became obvious to us, we began to carefully observe how it "works" among different peoples, why it is so, and why it gives such amazing results - and noticed one thing. In many countries (I'm talking about America, of course) they look not only at the shape

---

of the Earth, but also at the "geometric mean radius" of the "drive" of the planets. It is the same wavelength (or height) of a point in many coordinate systems (for example, in a two-dimensional sine), which is used to calculate the "ellipsoidal orbit" near the Earth. And for a long time it was used like this (especially in America, then it spread to the USSR) simply because the radius of the Earth on both sides of the equator coincides exactly with this "weighted average radius from the ecliptic." But everything in this world is starting to change
